# DBMS

UNIT - 1

#### • Introduction:

- Introduction to database,
- Characteristics of Database approach,
- Advantages of using DBMS approach,
- Three-schema architecture and data independence.
- DBMS Architecture.

#### What is Database???

• A **Database** is a collection of related data organized in a way that data can be easily accessed, managed and updated.

- A database can be of any size and complexity.
  - Phone numbers stored in SIM memory
  - Phone numbers stored on Memory card.
- A database may be generated and maintained manually or it may be computerized.
  - Library cards in your colleges (PUC)
  - Library cards in GIT

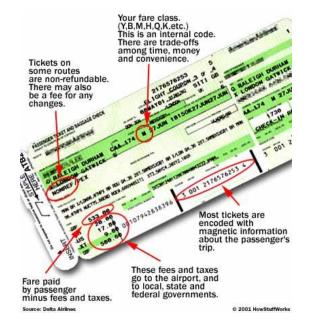

# Other databases you may use

amazon.com.

# Implicit properties of Database

- It represents some aspects of real world.
- It is logically collection of data with some inherent meaning.
- It is designed, built and populated with data for a specific purpose.

# Implicit properties of Database

• It represents some aspects of real world.

• It is logically collection of data with some inherent meaning.

• It is designed, built and populated with data for a specific purpose.

### What is DBMS???

• A **DBMS** is a software that allows creation, definition and manipulation of database. Dbms is actualy a tool used to perform any kind of operation on data in database. Dbms also provides protection and security to database. It maintains data consistency in case of multiple users. Here are some examples of popular dbms, MySql, Oracle, Sybase, Microsoft Access and

ORACLE

# Typical DBMS Functionality

- Define a database: in terms of data types, structures and constraints
- Construct or Load the Database on a secondary storage medium
- Manipulating the database: querying, generating reports, insertions, deletions and modifications to its content
- Concurrent Processing and Sharing by a set of users and programs – yet, keeping all data valid and consistent

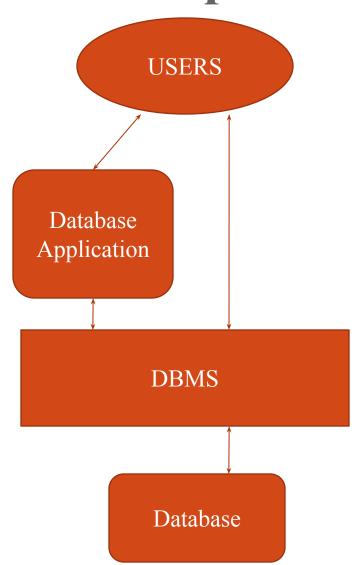

#### Other features:

- Protection or Security measures to prevent unauthorized access
- "Active" processing to take internal actions on data
- Presentation and Visualization of data

#### **Examples of Database Applications**

- Purchases using your credit card
- Booking a holiday at the travel agents
- Using the local library
- Taking out insurance
- Using the Internet
- Studying at university
- Many more ......

# **Components of Database System**

- Users: Users may be of various type such as DB administrator, System developer and End users.
- Database application: Database application may be Personal, Departmental, Enterprise and Internal
- DBMS: Software that allow users to define, create and manages database access, Ex: MySql, Oracle etc.
- Database: Collection of logical data.

# Characteristics of the Database Approach

- <u>Self-describing nature of a database system:</u> A DBMS **catalog** stores the *description* of the database. The description is called (**meta-data**). This allows the DBMS software to work with different databases.
- <u>Insulation between programs and data:</u> Called **program-data independence**. Allows changing data storage structures and operations without having to change the DBMS access programs.
- <u>Data Abstraction:</u> A **data model** is used to hide storage details and present the users with a *conceptual view* of the database.
- <u>Support of multiple views of the data:</u> Each user may see a different view of the database, which describes *only* the data of interest to that user.

• Sharing of data and multiuser transaction processing: allowing a set of concurrent users to retrieve and to update the database. Concurrency control within the DBMS guarantees that each **transaction** is correctly executed or completely aborted. OLTP (Online Transaction Processing) is a major part of database applications

#### Actors on the scene

- Database administrators: responsible for authorizing access to the database, for co-ordinating and monitoring its use, acquiring software, and hardware resources, controlling its use and monitoring efficiency of operations.
- Database Designers: responsible to define the content, the structure, the constraints, and functions or transactions against the database. They must communicate with the end-users and understand their needs.
- End-users: they use the data for queries, reports and some of them actually update the database content.
  - a) Casual end users (Managers)
  - b)Parametric end users( Accountant )
  - c) Sophisticated end users (Engineers)
  - d) Stand-alone end users (Users)

#### Actors on the scene

- Database administrators: responsible for authorizing access to the database, for co-ordinating and monitoring its use, acquiring software, and hardware resources, controlling its use and monitoring efficiency of operations.
- Database Designers: responsible to define the content, the structure, the constraints, and functions or transactions against the database. They must communicate with the end-users and understand their needs.

#### Workers behind the scene

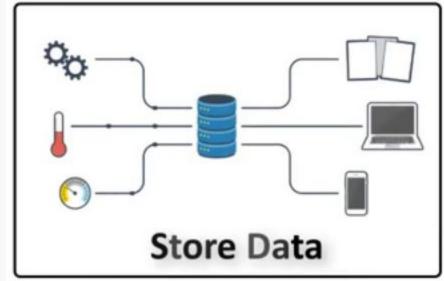

- DBMS System designer and implementers: design and implement the DBMS modules and interfaces as a software package. It includes: catlogs, query processing, interfaces, accessing data, data recovery and security.
- Tool developers: designs and implements tools. They include packages for database design, performance monitoring, simulations, test data generation.
- Operators and maintenance personnel: are responsible for actually running and maintenance of the hardware and software environment of the database system.

# Advantages of Using the Database Approach

- Controlling redundancy in data storage and in development and maintenance efforts.
- Sharing of data among multiple users.
- Restricting unauthorized access to data.
- Providing persistent storage for program Objects
- Providing Storage Structures for efficient Query Processing
- Providing backup and recovery services.
- Providing multiple interfaces to different classes of users.
- Representing complex relationships among data.
- Enforcing integrity constraints on the database.
- Drawing Inferences and Actions using rules

## DBMS ARCHITECTURE

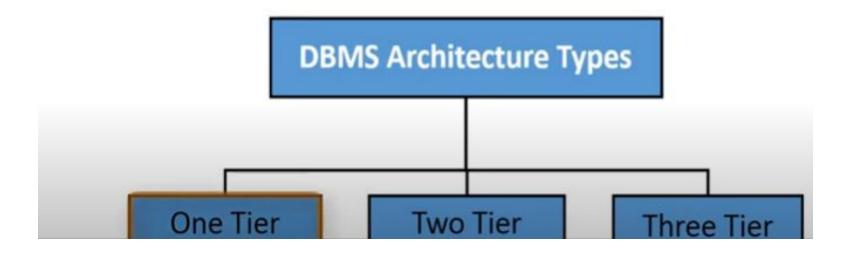

- The design of DBMS depends on its architecture.
- Architecture controls how to store and how to use data.

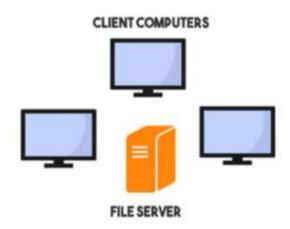

## DBMS ARCHITECTURE

- Its divided logically into 3 types:
  - One Tier
  - Two Tier
  - Three Tier

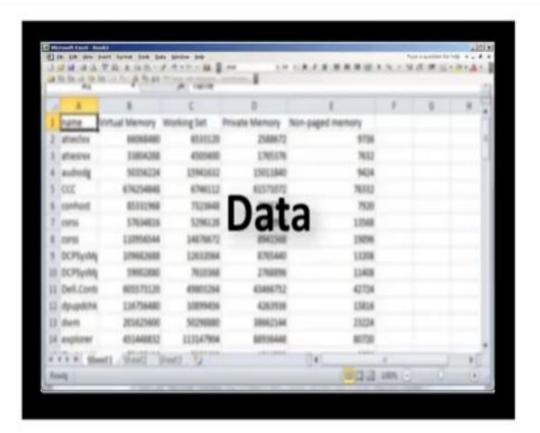

### One Tier Architecture

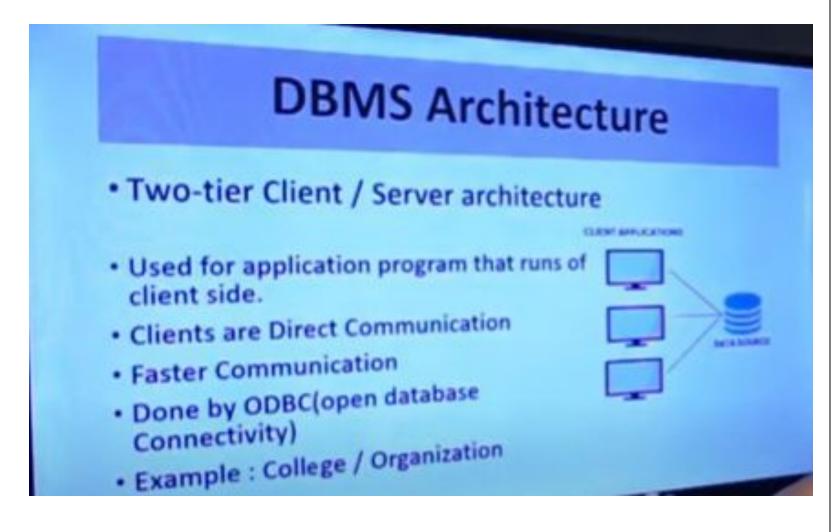

- All in one computer
- Application
- Data
- Presentation
  - Eg: MS office

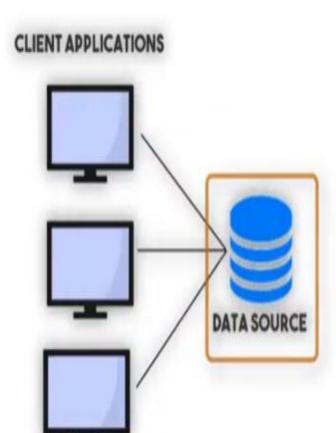

### Two Tier Architecture

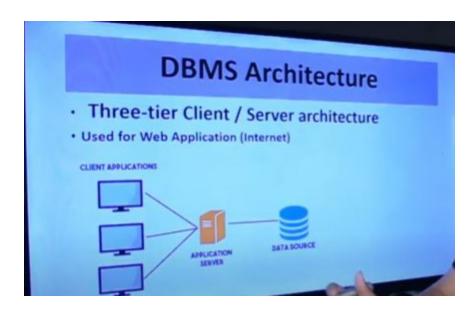

- Two computers
  - One client
  - One server

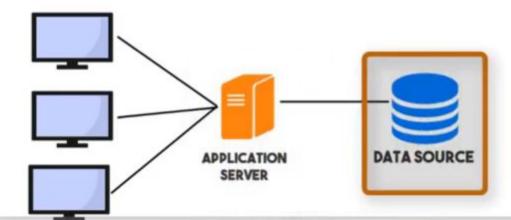

# Example

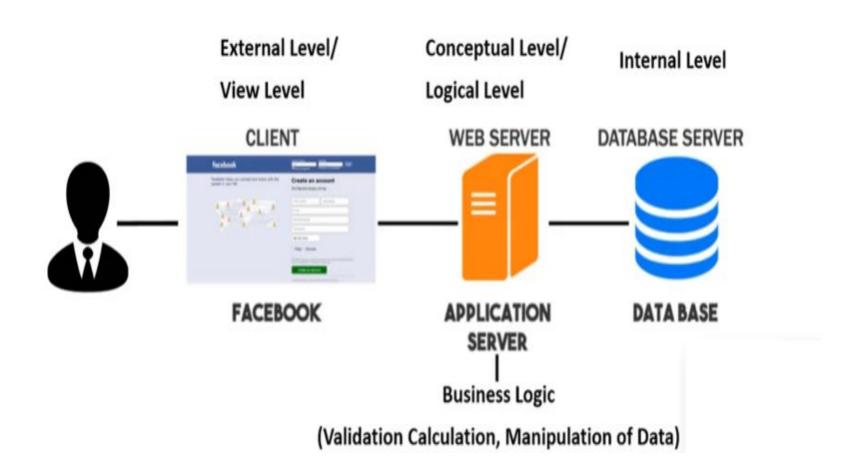

## Three Tier Architecture

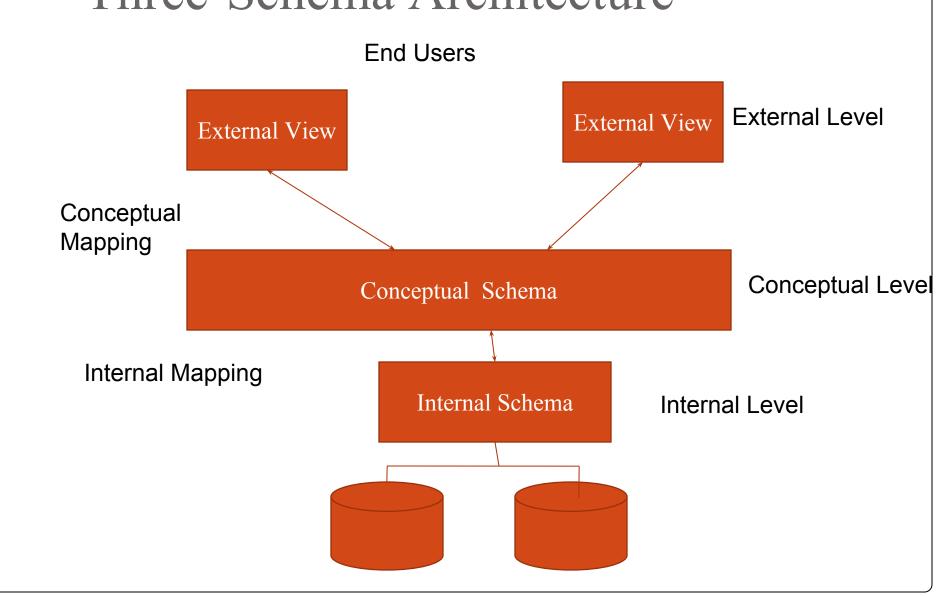

#### **CLIENT APPLICATIONS**

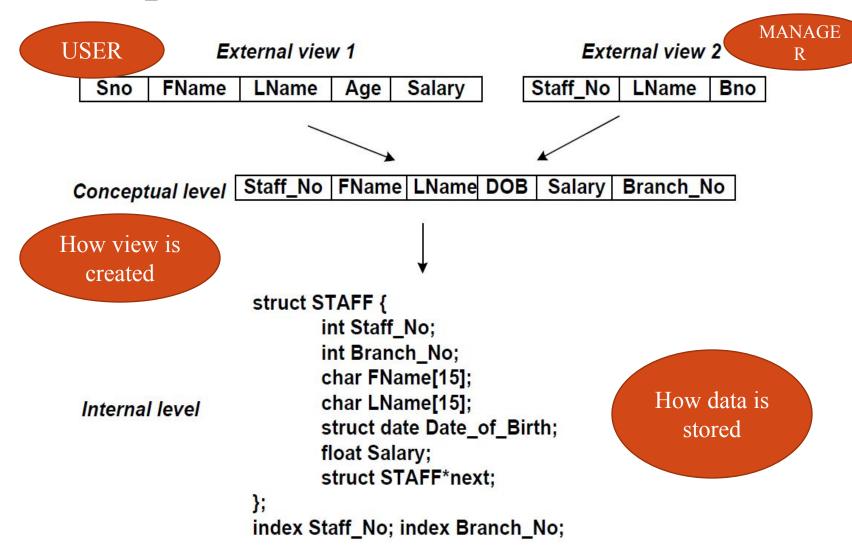

# example

#### Three-Schema Architecture

# Example of 3 Schema Architecture

#### EXTERNAL LEVEL (highest level)

- The user's view of the database.
- Consists of a number of different external views of the DB.
- Describes part of the DB for particular group of users.
- Provides a powerful and flexible security mechanism by hiding parts of the DB from certain users.
- It permits users to access data in a way that is customized to their needs, so that the same data can be seen by different users in different ways, at the same time.

#### CONCEPTUAL LEVEL

- The logical structure of the entire database as seen by DBA
- What data is stored in the database
- The relationships among the data
- Represents:
  - entities, attributes, relations
  - constraints on data
  - semantic information on data
  - security, integrity information

#### INTERNAL LEVEL

- Physical representation of the DB on the computer
- How the data is stored in the database
- Storage space allocation for data and indexes
- Data compression, encryption
- Record description for storage

#### Three-Schema Architecture

- Defines DBMS schemas at three levels:
  - **Internal schema** at the internal level to describe physical storage structures and access paths. Typically uses a *physical* data model.
  - Conceptual schema at the conceptual level to describe the structure and constraints for the *whole* database for a community of users. Uses a *conceptual* or an *implementation* data model.
  - External schemas at the external level to describe the various user views. Usually uses the same data model as the conceptual level.

# Data Independence

- Logical Data Independence: The capacity to change the conceptual schema without having to change the external schemas and their application programs.
- Physical Data Independence: The capacity to change the internal schema without having to change the conceptual schema.

#### When not to use a DBMS

#### • Main inhibitors (costs) of using a DBMS:

- High initial investment and possible need for additional hardware.
- Overhead for providing generality, security, concurrency control, recovery, and integrity functions.

#### When a DBMS may be unnecessary:

- If the database and applications are simple, well defined, and not expected to change.
- If access to data by multiple users is not required.

#### When no DBMS may suffice:

• If the database system is not able to handle the complexity of data because of modeling limitations
